

Basically the same. Allowed pen to continue for 1 full hour.

0.193g of

Ben pen materials were latex next to impossible to break up except when Methocel was added. These methocel was added to the form already with additional CH_2Cl_2 - very little gas evolution was generated etc.

Richard B.S.

For this mechanism of my suspension pen I figure that whether directly entering micelles of monomer excess solvent could form smaller micelles that could somehow transfer initiator solution to growing polymer particles or monomer micelles will not break up. Anyway - I figure it is possible to have these basic particles in the pen mixture
